

Parallel FEFF calculations

Kaifeng Zheng

The motivation

- Heavy calculation for large particles(XANES and EXAFS)

3000 147-atom particles contain 441,000 atoms
Each calculation uses roughly 1 min(single cpu).
3000 147-atom particles contain 441,000 atoms
441,000 atoms need 306.25 days to finish all calculations!!!

Solution: make the calculation parallel!

Multi-tasking FEFF calculations

Concurrent.futures

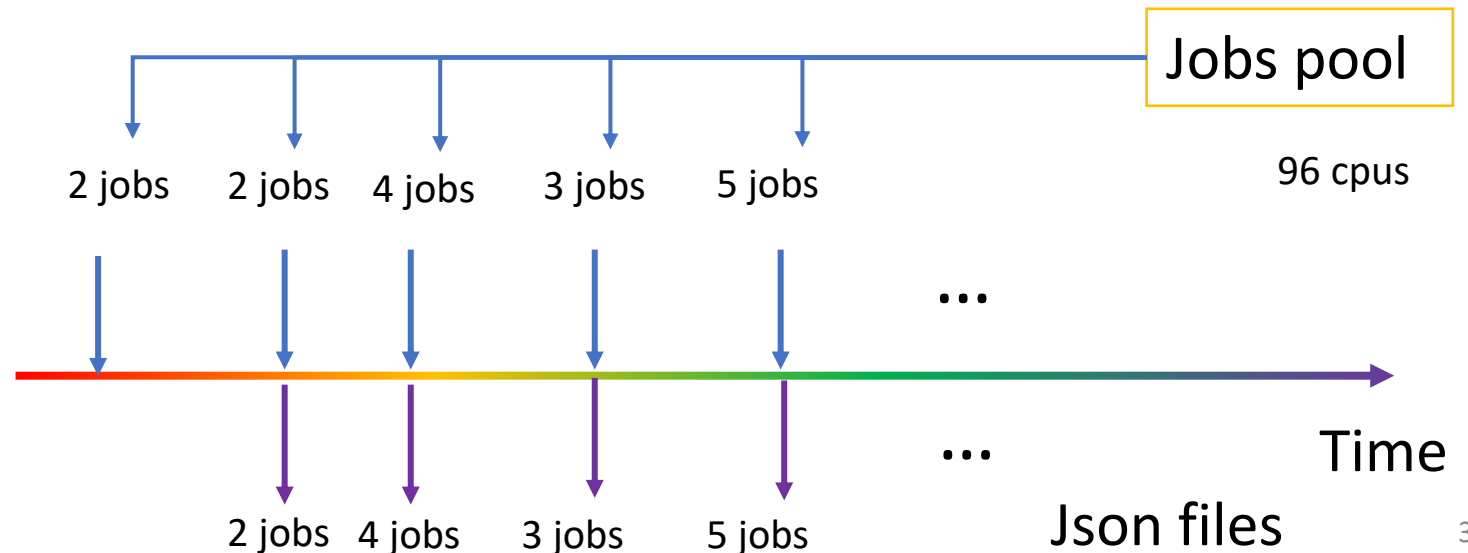

- Each particle has inequivalent sites
- Particles with different shape

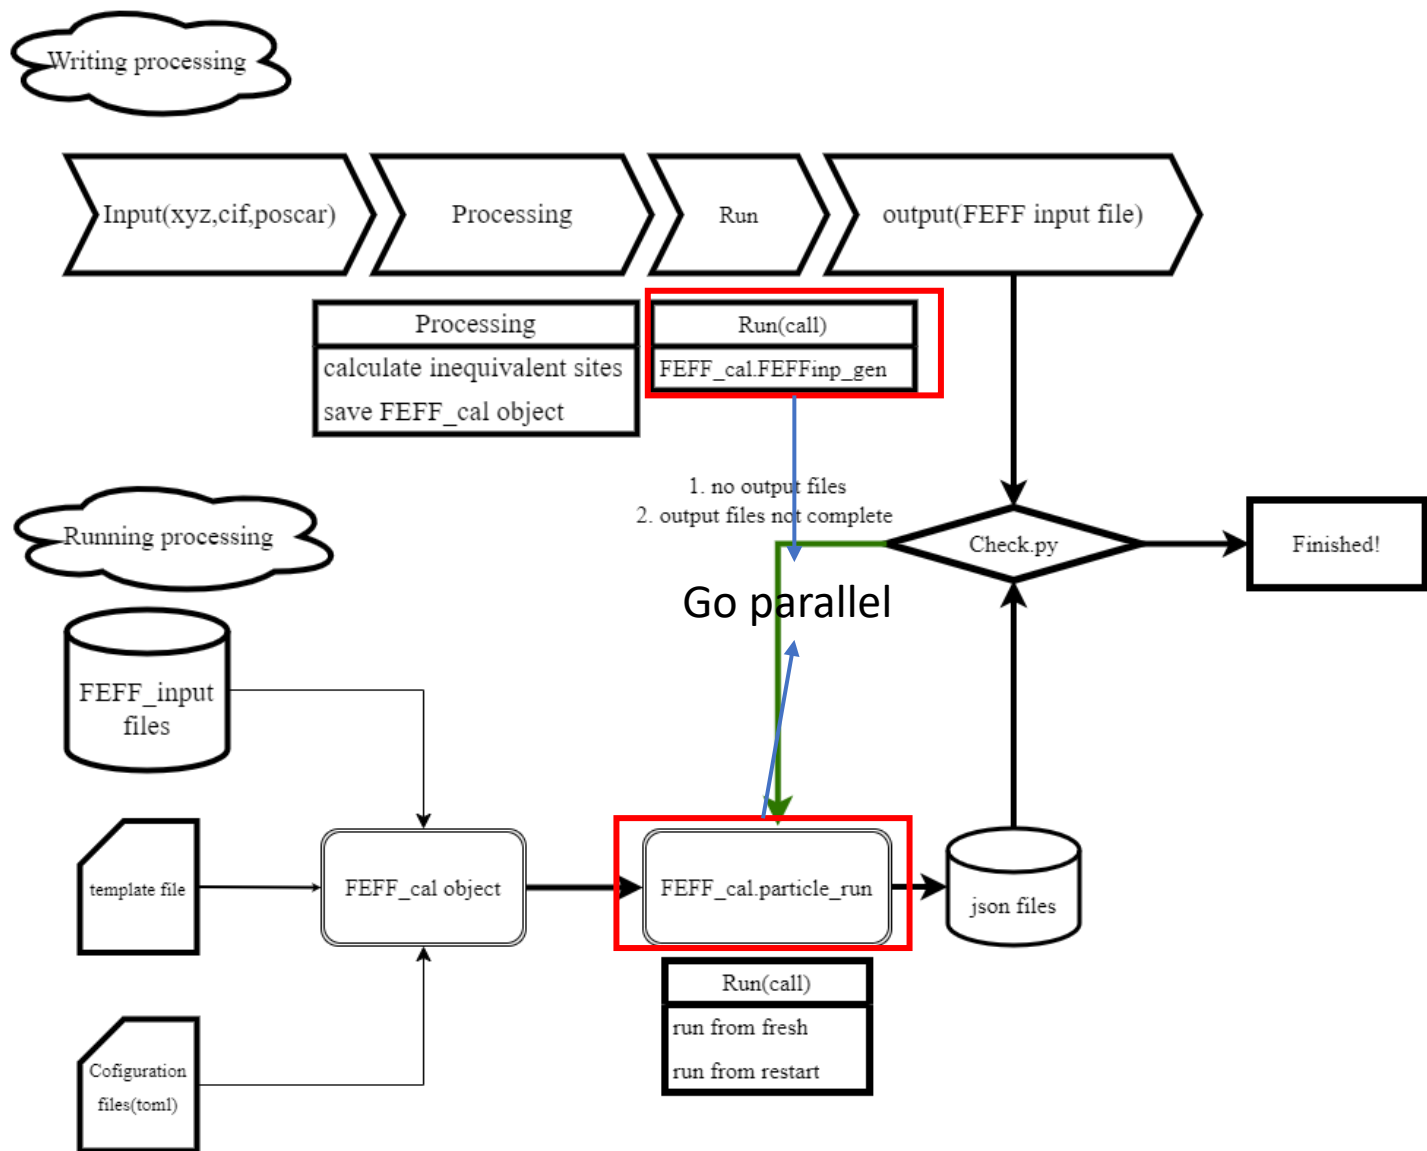

- Successful example
 - 55000 FEFF calculations for 55-atom particles need 32hrs to finish, which means 1 min finish 28 jobs!

Accelerate FEFF calculations by running multiple jobs simultaneously.

- Calculate Averaged spectrum for each particle after the calculation

The workflow of calculations

FEFF_cal object

functions

FEFFinput_gen: write FEFF input files
Particle_run: run FEFF calculations

Notes

1. We can specific absorber site or calculate sites based on symmetry
2. The input files can be xyz, cif, poscar
3. The code is easy to transfer to another project(XANES, EXAFS)
4. Template file contains the FEFF input header

Toolbox

1. average(output: csv)
2. Check.py(delete error calculations)

The backdraw for using concurrent.futures

- It cannot run on multiple nodes.
- restrict us to run FEFF calculation on one 96 core node

Submit multiple slurm jobs

| Queue | Default run time | Max run time | Max # of nodes | Min # of nodes | Max # of simultaneous jobs per user |
|-----------------|------------------|--------------|----------------|----------------|-------------------------------------|
| debug-28core | 1 hour | 1 hour | 8 | n/a | n/a |
| extended-24core | 8 hours | 7 days | 2 | n/a | 4 |
| extended-28core | 8 hours | 7 days | 2 | n/a | 6 |

Beyond concurrent.futures

```
from mpi4py import MPI
from mpi4py import MPIExecutor
```

mpi4py MPI for python package

mpipool Offers MPI based parallel execution of tasks through implementations of Python's standard library interfaces such as multiprocessing and concurrent.futures

comm=MPI.COMM_WORLD

rank=comm.Get_rank() ← Get CPU tag

pro_size=comm.Get_size() ← Get Pool size

Name=MPI.Get_processor_name() ← Get node name

Some concepts for parallel computing:

```
mpirun -n 240 python -m mpi4py FEFF_run_v3.py -w/-r
```

Rank:

Host:

Rank 0

→ Inequivalent sites calculations, read files...

Rank 1

Rank 2

Rank 3

...

Rank n

From rank=0:

comm.send(data,dest=i,tag=i)

To rank=i:

Comm.recv(source=0,tag=rank)

Writing and running processes...

Some results

Particle_site name

CPU name I'm running on

```

Finished 60465 sites on 100-atom particles with in 24 hr on 240 cpus(6 40core partition). Total:299686 needs 5 days

- Old result
 - 55000 FEFF calculations for 55-atom particles need 32hrs to finish, which means 1 min finish 28 jobs!

Configurations

```
#specific directory
template_dir = "template.inp"
scratch = "/gpfs/scratch//FEFF"
name='test_200'

#specific the method for writting FEFF inputfiles
particle='particle' #atom: specific site, particle: finding the inequivalent sites
CA = "Pt" #absorber atom type
radius = 100 #How large of the size of particle for this calculation

cutoff = 9 #radius for calculating symmetry using distance matrix method.
file_type="*.xyz" #specific the format of input file(we can also use cif, POSCAR)

#calculation specifcation
mode = "seq_multi"#the method to use(seq_seq, seq_multi,multi_multi and multi_seq)
cores = 1#number of cpu to use(unused)
tasks = 1#number of tasks go parallel(unused)
site = [19] #site should greater than or equal to 1(use it if you don't want to calculate inequivalent sites)
restart=false

#run SCF_test to check rSCF and rFMS
SCF_test=false
#rSCF=[5,7,8,9,10,15]
#rFMS=[3,5,7,8,9,10,12,15,17,20]
#rSCF=[3,4]
#rFMS=[3,4]

####future####
average=false
```

Specific the running directory

Note:
1st: sequential(seq)/parallel(multi)
2nd:sequential(seq)/parallel(multi)
for FEFF calculation

Do we get the unlimited speed to calculate FEFF?

No!

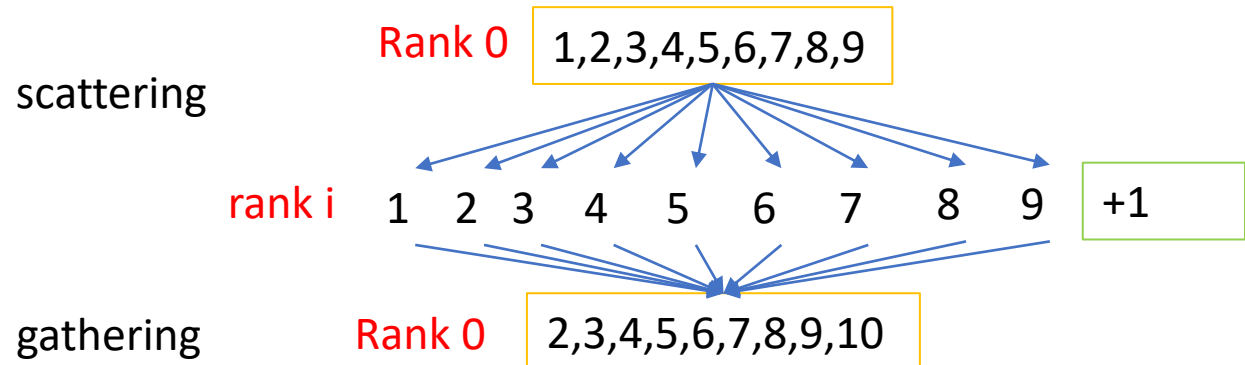

The communication between nodes are slow. I tried to parallel on 1000 cpus, it was not work. It takes forever to start.

For writing process, I used two methods to calculate inequivalent sites: point group(support in Pymatgen(very slow for large particle)), distance matrix(consider a partial structure within a radius of a particle to get inequivalent sites(fast but not accurate))

Future:

1. Update the codes by using parallel features(scattering, broadcasting, gathering...)
2. Optimize our algorithms for writing and running(I/O operations are very slow).

The functionality of my codes

- 1. calculate site-specific or particle-averaged spectrum
- 2. two symmetry calculations are available(point-group and distance matrix)
- 3. we can restart the calculation from the checkpoint.
- 4. there is a SCF-test calculation for FEFF parameters available in the code.
- 5. it can read from xyz, cif, and POSCAR.

My codes:

https://github.com/kaifengZheng/FEFF_package.git
